# Origins of Practice

- Spreadsheets have been used (and abused) for many purposes over time.
- Convenient way to edit and maintain small amounts of tabular data
- ... Sometimes grows to too much data
- ... Sometimes used for non-tabular data

# Origins of Practice

- W3C maintains many small vocabularies
  - Specifications may define namespaces with terms
  - Test Suites may extend other test suites and/or need to reduce to available datasets for processing (e.g., EARL reports)

# Uses of Vocabularies

- Machine-readable metadata
  - Classes, Properties, Datatypes, Domains, Ranges
- Human-readable
  - Developer Documentation
- Generate/maintain JSON-LD Contexts
  - Context can include the full vocabulary definition extractable as RDF

# General Approaches

- No vocabulary document (described in prose only)
- Manage RDF serializations by hand (RDF/XML, Turtle, JSON-LD)
- Use Protégé
- Create alternate representations automatically
  - Possible for RDF/XML, Turtle, N-Triples
  - Awkward for RDFa or JSON-LD
- Use a convenient non-RDF representation to derive other formats
  - Spreadsheets!

# No vocabulary

- Example: RDFa Processor Status<sup>\*</sup>
  - Advantages: Simple for editor
  - Disadvantages: No machine-readable representation
- An `rdfa:Error` **must** be generated when the document fails to be fully processed as a result of non-conformant Host Language markup.
- A `rdfa:Warning` **must** be generated when a CURIE prefix fails to be resolved.
- A `rdfa:Warning` **must** be generated when a Term fails to be resolved.

<sup>\*</sup> <https://www.w3.org/TR/rdfa-core/#processor-status>

# Hand-built vocabulary

- Example: RDF Schema\*
- Advantages: Simpler for spec editor.
- Disadvantages: HTML and N-Triples not maintained together. HTML not machine-readable

All things described by RDF are called *resources*, and are instances of the class `rdfs:Resource`. This is the class of everything. All other classes are subclasses of this class. `rdfs:Resource` is an instance of `rdfs:Class`.

```
rdfs:Resource a rdfs:Class ;  
rdfs:isDefinedBy <http://www.w3.org/2000/01/rdf-schema#> ;  
rdfs:label "Resource" ;  
rdfs:comment "The class resource, everything." .
```

\* [https://www.w3.org/TR/2014/REC-rdf-schema-20140225/#ch\\_resource](https://www.w3.org/TR/2014/REC-rdf-schema-20140225/#ch_resource)

# Protégé

- Great tool for managing complex vocabularies
- Advantages: WYSIWYG ontology development. Fully supported tool.
- Disadvantages: Little control over serialization. Details can get lost in UI.

# RDF Source Document

- Example: JSON-LD Test-Suite<sup>\*</sup>
  - Hand maintain Turtle RDFS document and JSON-LD context
  - Direct transform Turtle to JSON-LD
  - Use Haml template to generate HTML from JSON-LD.
  - Advantages: Single source, consistency
  - Disadvantages: Context made by hand. JSON-LD may not be convenient.

<sup>\*</sup> <https://github.com/json-ld/json-ld.org/tree/master/test-suite>

# Vocabulary in CSV

- Examples: CSVW[1], ShEx[2]
  - Information in spreadsheet
  - script creates JSON object indexed by type
  - after processing, objects gathered into JSON-LD to describe both context and vocabulary
  - Custom Turtle generation
  - Haml template-based HTML generation

# RDF.rb serialization support

- Ruby RDF.rb internalizes RDFS+ vocabularies for convenience and reasoning
  - Read and RDF serialization to create Vocabulary
  - Vocabulary supports .to\_ttl, .to\_jsonld, and .to\_html with reasonable defaults which may be customized
